

DUETACT

(pioglitazone and glimepiride) tablets

Rx only

WARNING: CONGESTIVE HEART FAILURE

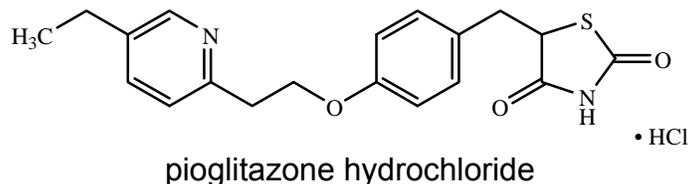

- Thiazolidinediones, including pioglitazone, which is a component of DUETACT, cause or exacerbate congestive heart failure in some patients (see **WARNINGS, Pioglitazone**). After initiation of DUETACT, observe patients carefully for signs and symptoms of heart failure (including excessive, rapid weight gain, dyspnea, and/or edema). If these signs and symptoms develop, the heart failure should be managed according to the current standards of care. Furthermore, discontinuation of DUETACT must be considered.
- DUETACT is not recommended in patients with symptomatic heart failure. Initiation of DUETACT in patients with established NYHA Class III or IV heart failure is contraindicated (see **CONTRAINDICATIONS** and **WARNINGS, Pioglitazone**).

DESCRIPTION

DUETACT (pioglitazone and glimepiride) tablets contain two oral antihyperglycemic agents used in the management of type 2 diabetes: pioglitazone and glimepiride. The concomitant use of pioglitazone and a sulfonylurea, the class of drugs that includes glimepiride, has been previously approved based on clinical trials in patients with type 2 diabetes inadequately controlled on a sulfonylurea. Additional efficacy and safety information about pioglitazone and glimepiride monotherapies may be found in the prescribing information for each individual drug.

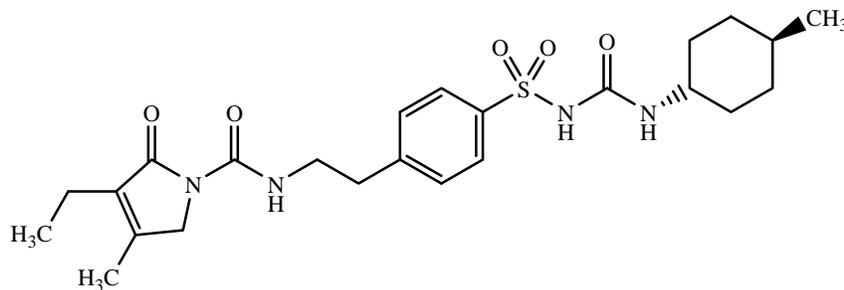

Pioglitazone is an oral antihyperglycemic agent that acts primarily by decreasing insulin resistance. Pioglitazone is used in the management of type 2 diabetes. Pharmacological studies indicate that pioglitazone improves sensitivity to insulin in muscle and adipose tissue and inhibits hepatic gluconeogenesis. Pioglitazone improves glycemic control while reducing circulating insulin levels.

Pioglitazone (\pm)-5-[[4-[2-(5-ethyl-2-pyridinyl)ethoxy]phenyl]methyl]-2,4-thiazolidinedione monohydrochloride belongs to a different chemical class and has a different pharmacological action than the sulfonylureas, biguanides, or the α -glucosidase inhibitors. The molecule contains one asymmetric center, and the synthetic compound is a racemate. The two enantiomers of pioglitazone interconvert *in vivo*. The structural formula is as shown:

Pioglitazone hydrochloride is an odorless, white crystalline powder that has a molecular formula of $C_{19}H_{20}N_2O_3S \cdot HCl$ and a molecular weight of 392.90. It is soluble in *N,N*-dimethylformamide, slightly soluble in anhydrous ethanol, very slightly soluble in acetone and acetonitrile, practically insoluble in water, and insoluble in ether.

Glimepiride 1-[[*p*-[2-(3-ethyl-4-methyl-2-oxo-3-pyrroline-1-carboxamido)ethyl]phenyl]sulfonyl]-3-(*trans*-4-methylcyclohexyl)-urea is an oral blood glucose-lowering drug of the sulfonylurea class and is used in the management of type 2 diabetes. The molecule is the *trans*-isomer with respect to the cyclohexyl substituents. The chemical structure is as shown:

glimepiride

Glimepiride is a white to yellowish-white crystalline, odorless to practically odorless powder, that has a molecular formula of $C_{24}H_{34}N_4O_5S$ and a molecular weight of 490.62. It is soluble in dimethylsulfoxide, slightly soluble in acetone, very slightly soluble in acetonitrile and methanol, and practically insoluble in water.

DUETACT is available as a tablet for oral administration containing 30 mg pioglitazone (as the base) with 2 mg glimepiride (30 mg/2 mg) or 30 mg pioglitazone (as the base) with 4 mg glimepiride (30 mg/4 mg) formulated with the following excipients: croscarmellose sodium NF, lactose monohydrate NF, magnesium stearate NF, hydroxypropyl cellulose NF, polysorbate 80 NF, and microcrystalline cellulose NF.

CLINICAL PHARMACOLOGY

Mechanism of Action

DUETACT

DUETACT combines two antihyperglycemic agents with different mechanisms of action to improve glycemic control in patients with type 2 diabetes: pioglitazone, a member of the thiazolidinedione class, and glimepiride, a member of the sulfonylurea class.

Thiazolidinediones are insulin-sensitizing agents that act primarily by enhancing peripheral glucose utilization, whereas sulfonylureas are insulin secretagogues that act primarily by stimulating release of insulin from functioning pancreatic beta cells.

Pioglitazone

Pioglitazone depends on the presence of insulin for its mechanism of action.

Pioglitazone decreases insulin resistance in the periphery and in the liver resulting in increased insulin-dependent glucose disposal and decreased hepatic glucose output.

Pioglitazone is a potent and highly selective agonist for peroxisome proliferator-

activated receptor-gamma (PPAR γ). PPAR receptors are found in tissues important for insulin action such as adipose tissue, skeletal muscle, and liver. Activation of PPAR γ nuclear receptors modulates the transcription of a number of insulin-responsive genes involved in the control of glucose and lipid metabolism.

In animal models of diabetes, pioglitazone reduces the hyperglycemia, hyperinsulinemia, and hypertriglyceridemia characteristic of insulin-resistant states such as type 2 diabetes. The metabolic changes produced by pioglitazone result in increased responsiveness of insulin-dependent tissues and are observed in numerous animal models of insulin resistance.

Since pioglitazone enhances the effects of circulating insulin (by decreasing insulin resistance), it does not lower blood glucose in animal models that lack endogenous insulin.

Glimepiride

The primary mechanism of action of glimepiride in lowering blood glucose appears to be dependent on stimulating the release of insulin from functioning pancreatic beta cells. In addition, extrapancreatic effects may also play a role in the activity of sulfonylureas such as glimepiride. This is supported by both preclinical and clinical studies demonstrating that glimepiride administration can lead to increased sensitivity of peripheral tissues to insulin. These findings are consistent with the results of a long-term, randomized, placebo-controlled trial in which glimepiride therapy improved postprandial insulin/C-peptide responses and overall glycemic control without producing clinically meaningful increases in fasting insulin/C-peptide levels. However, as with other sulfonylureas, the mechanism by which glimepiride lowers blood glucose during long-term administration has not been clearly established.

Pharmacokinetics and Drug Metabolism

Absorption and Bioavailability

DUETACT

Bioequivalence studies were conducted following a single dose of the DUETACT 30 mg/2 mg and 30 mg/4 mg tablets and concomitant administration of ACTOS (30 mg) and glimepiride (2 mg or 4 mg) under fasting conditions in healthy subjects.

Based on the area under the curve (AUC) and maximum concentration (C_{max}) of both pioglitazone and glimepiride, DUETACT 30 mg/2 mg and 30 mg/4 mg were bioequivalent to ACTOS 30 mg concomitantly administered with glimepiride (2 mg or 4 mg, respectively) (*Table 1*).

Table 1. Mean (SD) Pharmacokinetic Parameters for DUETACT

Regimen		N	AUC _(0-inf) (ng·h/mL)	N	C _{max} (ng/mL)	N	T _{max} (h)	N	T _{1/2} (h)
30 mg/2 mg DUETACT	pioglitazone	58	11414 (2704)	66	910 (336)	66	1.81 (1.11)	65	14.02 (6.23)
	glimepiride	62	651 (239)	66	156 (52.5)	66	1.39 (0.29)	63	7.05 (4.32)
30 mg pioglitazone + 2 mg glimepiride tablets	pioglitazone	58	11496 (2926)	66	975 (367)	66	1.48 (1.13)	65	12.71 (5.60)
	glimepiride	62	635 (240)	66	165 (53.1)	66	1.36 (0.35)	63	5.54 (4.21)
30 mg/4 mg DUETACT	pioglitazone	55	11119 (3399)	67	1062 (333)	67	1.53 (0.81)	67	10.88 (4.71)
	glimepiride	64	1645 (576)	67	319 (95.3)	67	1.45 (0.39)	64	10.52 (3.49)
30 mg pioglitazone + 4 mg glimepiride tablets	pioglitazone	55	10674 (2895)	67	1026 (346)	67	1.52 (1.95)	67	12.21 (6.30)
	glimepiride	64	1590 (554)	67	313 (97.8)	67	1.76 (1.13)	64	9.07 (3.47)

Food did not change the systemic exposures of glimepiride or pioglitazone following administration of DUETACT. The presence of food did not significantly alter the time to peak serum concentration of glimepiride or pioglitazone or peak exposure (C_{max}) of pioglitazone. However, for glimepiride, there was a 22% increase in C_{max} when DUETACT was administered with food.

Pioglitazone

Following oral administration, in the fasting state, pioglitazone is first measurable in serum within 30 minutes, with peak concentrations observed within two hours.

Glimepiride

After oral administration, glimepiride is completely (100%) absorbed from the GI tract. Studies with single oral doses in normal subjects and with multiple oral doses in patients with type 2 diabetes have shown significant absorption of glimepiride within one hour after administration and C_{max} at two to three hours.

Distribution

Pioglitazone

The mean apparent volume of distribution (V_d/F) of pioglitazone following single-dose administration is 0.63 ± 0.41 (mean ± SD) L/kg of body weight. Pioglitazone is extensively protein bound (>99%) in human serum, principally to serum albumin.

Pioglitazone also binds to other serum proteins, but with lower affinity. Metabolites M-III and M-IV also are extensively bound (>98%) to serum albumin.

Glimepiride

After intravenous (IV) dosing in normal subjects, Vd/F was 8.8 L (113 mL/kg), and the total body clearance (CL) was 47.8 mL/min. Protein binding was greater than 99.5%.

Metabolism

Pioglitazone

Pioglitazone is extensively metabolized by hydroxylation and oxidation; the metabolites also partly convert to glucuronide or sulfate conjugates. Metabolites M-II and M-IV (hydroxy derivatives of pioglitazone) and M-III (keto derivative of pioglitazone) are pharmacologically active in animal models of type 2 diabetes. In addition to pioglitazone, M-III and M-IV are the principal drug-related species found in human serum following multiple dosing. At steady-state, in both healthy volunteers and in patients with type 2 diabetes, pioglitazone comprises approximately 30% to 50% of the total peak serum concentrations and 20% to 25% of the total AUC.

In vitro data demonstrate that multiple CYP isoforms are involved in the metabolism of pioglitazone. The cytochrome P450 isoforms involved are CYP2C8 and, to a lesser degree, CYP3A4 with additional contributions from a variety of other isoforms including the mainly extrahepatic CYP1A1. *In vivo* studies of pioglitazone in combination with P450 inhibitors and substrates have been performed (see **PRECAUTIONS, Drug Interactions, Pioglitazone**). Urinary 6 β -hydroxycortisol/cortisol ratios measured in patients treated with pioglitazone showed that pioglitazone is not a strong CYP3A4 enzyme inducer.

Glimepiride

Glimepiride is completely metabolized by oxidative biotransformation after either an IV or oral dose. The major metabolites are the cyclohexyl hydroxy methyl derivative (M1) and the carboxyl derivative (M2). CYP2C9 has been shown to be involved in the biotransformation of glimepiride to M1. M1 is further metabolized to M2 by one or several cytosolic enzymes. M1, but not M2, possesses about 1/3 of the pharmacological activity as compared to its parent in an animal model; however, whether the glucose-lowering effect of M1 is clinically meaningful is not clear.

Excretion and Elimination

Pioglitazone

Following oral administration, approximately 15% to 30% of the pioglitazone dose is recovered in the urine. Renal elimination of pioglitazone is negligible and the drug is excreted primarily as metabolites and their conjugates. It is presumed that most of the oral dose is excreted into the bile either unchanged or as metabolites and eliminated in the feces.

The mean serum half-life of pioglitazone and total pioglitazone ranges from three to seven hours and 16 to 24 hours, respectively. Pioglitazone has an apparent clearance, CL/f, calculated to be 5 to 7 L/hr.

Glimepiride

When ¹⁴C-glimepiride was given orally, approximately 60% of the total radioactivity was recovered in the urine in seven days and M1 (predominant) and M2 accounted for 80%

to 90% of that recovered in the urine. Approximately 40% of the total radioactivity was recovered in feces and M1 and M2 (predominant) accounted for about 70% of that recovered in feces. No parent drug was recovered from urine or feces. After IV dosing in patients, no significant biliary excretion of glimepiride or its M1 metabolite has been observed.

Special Populations

Renal Insufficiency

Pioglitazone

The serum elimination half-life of pioglitazone, M-III and M-IV remains unchanged in patients with moderate (creatinine clearance 30 to 60 mL/min) to severe (creatinine clearance <30 mL/min) renal impairment when compared to normal subjects. No dose adjustment in patients with renal dysfunction is recommended.

Glimepiride

A single-dose, open-label study was conducted in 15 patients with renal impairment. Glimepiride (3 mg) was administered to three groups of patients with different levels of mean creatinine clearance (CLCr); (Group I, CLCr = 77.7 mL/min, n = 5), (Group II, CLCr = 27.7 mL/min, n = 3), and (Group III, CLCr = 9.4 mL/min, n = 7). Glimepiride was found to be well tolerated in all three groups. The results showed that glimepiride serum levels decreased as renal function decreased. However, M1 and M2 serum levels (mean AUC values) increased 2.3 and 8.6 times from Group I to Group III. The apparent terminal half-life ($T_{1/2}$) for glimepiride did not change, while the half-lives for M1 and M2 increased as renal function decreased. Mean urinary excretion of M1 plus M2 as percent of dose, however, decreased (44.4%, 21.9% and 9.3% for Groups I to III).

A multiple-dose titration study was also conducted in 16 patients with type 2 diabetes and with renal impairment using doses ranging from 1 mg to 8 mg daily for three months. The results were consistent with those observed after single doses. All patients with a CLCr less than 22 mL/min had adequate control of their glucose levels with a dosage regimen of only 1 mg daily. The results from this study suggested that a starting dose of 1 mg glimepiride may be given to patients with type 2 diabetes and kidney disease, and the dose may be titrated based on fasting blood glucose levels (see **DOSAGE AND ADMINISTRATION, Special Patient Populations**).

Hepatic Insufficiency

Pioglitazone

Compared with normal controls, subjects with impaired hepatic function (Child-Pugh Grade B/C) have an approximate 45% reduction in pioglitazone and total pioglitazone mean peak concentrations but no change in the mean AUC values.

Therapy with DUETACT should not be initiated if the patient exhibits clinical evidence of active liver disease or serum transaminase levels (ALT) exceed 2.5 times the upper limit of normal (see **PRECAUTIONS, General, Pioglitazone, Hepatic Effects**).

Glimepiride

No studies were performed in patients with hepatic insufficiency.

Elderly***Pioglitazone***

In healthy elderly subjects, peak serum concentrations of pioglitazone and total pioglitazone are not significantly different, but AUC values are slightly higher and the terminal half-life values slightly longer than for younger subjects. These changes were not of a magnitude that would be considered clinically relevant.

Glimepiride

Comparison of glimepiride pharmacokinetics in patients with type 2 diabetes ≤ 65 years and those >65 years was performed in a study using a dosing regimen of 6 mg daily. There were no significant differences in glimepiride pharmacokinetics between the two age groups. The mean AUC at steady-state for the older patients was about 13% lower than that for the younger patients; the mean weight-adjusted clearance for the older patients was about 11% higher than that for the younger patients.

Pediatrics

No pharmacokinetic studies of DUETACT were performed in pediatric patients.

Gender***Pioglitazone***

As monotherapy and in combination with sulfonylurea, metformin or insulin, pioglitazone improved glycemic control in both males and females. The mean C_{max} and AUC values were increased 20% to 60% in females. In controlled clinical trials, hemoglobin A1C (A1C) decreases from baseline were generally greater for females than for males (average mean difference in A1C 0.5%). Since therapy should be individualized for each patient to achieve glycemic control, no dose adjustment is recommended based on gender alone.

Glimepiride

There were no differences between males and females in the pharmacokinetics of glimepiride when adjustment was made for differences in body weight.

Ethnicity***Pioglitazone***

Pharmacokinetic data among various ethnic groups are not available.

Glimepiride

No pharmacokinetic studies to assess the effects of race have been performed, but in placebo-controlled studies of glimepiride in patients with type 2 diabetes, the antihyperglycemic effect was comparable in whites (n = 536), blacks (n = 63) and Hispanics (n = 63).

Other Populations***Glimepiride***

There were no important differences in glimepiride metabolism in subjects identified as phenotypically different drug-metabolizers by their metabolism of sparteine. The pharmacokinetics of glimepiride in morbidly obese patients were similar to those in the normal weight group, except for a lower C_{max} and AUC. However, since neither C_{max} nor AUC values were normalized for body surface area, the lower values of C_{max} and AUC for the obese patients were likely the result of their excess weight and not due to a difference in the kinetics of glimepiride.

Drug-Drug Interactions

Coadministration of pioglitazone (45 mg) and a sulfonylurea (5 mg glipizide) administered orally once daily for seven days did not alter the steady-state pharmacokinetics of glipizide. Glimepiride and glipizide have similar metabolic pathways and are mediated by CYP2C9; therefore, drug-drug interaction between pioglitazone and glimepiride is considered unlikely. Specific pharmacokinetic drug interaction studies with DUETACT have not been performed, although such studies have been conducted with the individual pioglitazone and glimepiride components.

Pioglitazone

The following drugs were studied in healthy volunteers with coadministration of pioglitazone 45 mg once daily. Results are listed below:

Oral Contraceptives

Coadministration of pioglitazone (45 mg once daily) and an oral contraceptive (1 mg norethindrone plus 0.035 mg ethinyl estradiol once daily) for 21 days, resulted in 11% and 11% to 14% decrease in ethinyl estradiol AUC_{0-24h} and C_{max} respectively. There were no significant changes in norethindrone AUC_{0-24h} and C_{max}. In view of the high variability of ethinyl estradiol pharmacokinetics, the clinical significance of this finding is unknown.

Midazolam

Administration of pioglitazone for 15 days followed by a single 7.5 mg dose of midazolam syrup resulted in a 26% reduction in midazolam C_{max} and AUC.

Nifedipine ER

Coadministration of pioglitazone for seven days with 30 mg nifedipine ER administered orally once daily for four days to male and female volunteers resulted in a ratio of least square mean (90% CI) values for unchanged nifedipine of 0.83 (0.73 to 0.95) for C_{max} and 0.88 (0.80 to 0.96) for AUC. In view of the high variability of nifedipine pharmacokinetics, the clinical significance of this finding is unknown.

Ketoconazole

Coadministration of pioglitazone for seven days with ketoconazole 200 mg administered twice daily resulted in a ratio of least square mean (90% CI) values for unchanged pioglitazone of 1.14 (1.06 to 1.23) for C_{max}, 1.34 (1.26 to 1.41) for AUC and 1.87 (1.71 to 2.04) for C_{min}.

Atorvastatin Calcium

Coadministration of pioglitazone for seven days with atorvastatin calcium (LIPITOR) 80 mg once daily resulted in a ratio of least square mean (90% CI) values for unchanged pioglitazone of 0.69 (0.57 to 0.85) for C_{max}, 0.76 (0.65 to 0.88) for AUC and 0.96 (0.87 to 1.05) for C_{min}. For unchanged atorvastatin, the ratio of least square mean (90% CI) values were 0.77 (0.66 to 0.90) for C_{max}, 0.86 (0.78 to 0.94) for AUC and 0.92 (0.82 to 1.02) for C_{min}.

Cytochrome P450

See **PRECAUTIONS, Drug Interactions, Pioglitazone.**

Gemfibrozil

Concomitant administration of gemfibrozil (oral 600 mg twice daily), an inhibitor of CYP2C8, with pioglitazone (oral 30 mg) in 10 healthy volunteers pretreated for two days

prior with gemfibrozil (oral 600 mg twice daily) resulted in pioglitazone exposure (AUC_{0-24}) being 226% of the pioglitazone exposure in the absence of gemfibrozil (see **PRECAUTIONS, Drug Interactions, Pioglitazone**).¹

Rifampin

Concomitant administration of rifampin (oral 600 mg once daily), an inducer of CYP2C8 with pioglitazone (oral 30 mg) in 10 healthy volunteers pretreated for five days prior with rifampin (oral 600 mg once daily) resulted in a decrease in the AUC of pioglitazone by 54% (see **PRECAUTIONS, Drug Interactions, Pioglitazone**).²

In other drug-drug interaction studies, pioglitazone had no significant effect on the pharmacokinetics of fexofenadine, metformin, digoxin, warfarin, ranitidine or theophylline.

Glimepiride

The hypoglycemic action of sulfonylureas may be potentiated by certain drugs, including nonsteroidal anti-inflammatory drugs and other drugs that are highly protein bound, such as salicylates, sulfonamides, chloramphenicol, coumarins, probenecid, monoamine oxidase inhibitors and beta adrenergic blocking agents. Due to the potential drug interaction between these drugs and glimepiride, the patient should be observed closely for hypoglycemia when these drugs are coadministered. Conversely, when these drugs are withdrawn, the patient should be observed closely for loss of glycemic control.

Certain drugs tend to produce hyperglycemia and may lead to loss of control. These drugs include the thiazides and other diuretics, corticosteroids, phenothiazines, thyroid products, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, and isoniazid. Due to the potential drug interaction between these drugs and glimepiride, the patient should be observed closely for loss of glycemic control when these drugs are co-administered. Conversely, when these drugs are withdrawn, the patient should be observed closely for hypoglycemia.

Aspirin

Coadministration of aspirin (1 g three times daily) and glimepiride led to a 34% decrease in the mean glimepiride AUC and, therefore, a 34% increase in the mean CL/f. The mean C_{max} had a decrease of 4%. Blood glucose and serum C-peptide concentrations were unaffected and no hypoglycemic symptoms were reported. Pooled data from clinical trials showed no evidence of clinically significant adverse interactions with uncontrolled concurrent administration of aspirin and other salicylates.

Cimetidine/Ranitidine

Coadministration of either cimetidine (800 mg once daily) or ranitidine (150 mg twice daily) with a single 4-mg oral dose of glimepiride did not significantly alter the absorption and disposition of glimepiride, and no differences were seen in hypoglycemic symptomatology. Pooled data from clinical trials showed no evidence of clinically significant adverse interactions with uncontrolled concurrent administration of H₂-receptor antagonists.

Propranolol

Concomitant administration of propranolol (40 mg three times daily) and glimepiride significantly increased C_{max} , AUC and $T_{1/2}$ of glimepiride by 23%, 22%, and 15%,

respectively, and it decreased CL/f by 18%. The recovery of M1 and M2 from urine, however, did not change. The pharmacodynamic responses to glimepiride were nearly identical in normal subjects receiving propranolol and placebo. Pooled data from clinical trials in patients with type 2 diabetes showed no evidence of clinically significant adverse interactions with uncontrolled concurrent administration of beta-blockers. However, if beta-blockers are used, caution should be exercised and patients should be warned about the potential for hypoglycemia.

Warfarin

Concomitant administration of glimepiride (4 mg once daily) did not alter the pharmacokinetic characteristics of R- and S-warfarin enantiomers following administration of a single dose (25 mg) of racemic warfarin to healthy subjects. No changes were observed in warfarin plasma protein binding. Glimepiride treatment did result in a slight, but statistically significant, decrease in the pharmacodynamic response to warfarin. The reductions in mean area under the prothrombin time (PT) curve and maximum PT values during glimepiride treatment were very small (3.3% and 9.9%, respectively) and are unlikely to be clinically important.

Ramipril

The responses of serum glucose, insulin, C-peptide and plasma glucagon to 2 mg glimepiride were unaffected by coadministration of ramipril (an ACE inhibitor) 5 mg once daily in normal subjects. No hypoglycemic symptoms were reported. Pooled data from clinical trials in patients with type 2 diabetes showed no evidence of clinically significant adverse interactions with uncontrolled concurrent administration of ACE inhibitors.

Miconazole

A potential interaction between oral miconazole and oral hypoglycemic agents leading to severe hypoglycemia has been reported. Whether this interaction also occurs with the intravenous, topical, or vaginal preparations of miconazole is not known. There is a potential interaction of glimepiride with inhibitors (e.g., fluconazole) and inducers (e.g., rifampicin) of cytochrome P450 2C9.

Although no specific interaction studies were performed with glimepiride, pooled data from clinical trials showed no evidence of clinically significant adverse interactions with uncontrolled concurrent administration of calcium-channel blockers, estrogens, fibrates, NSAIDs, HMG CoA reductase inhibitors, sulfonamides or thyroid hormone.

Pharmacodynamics and Clinical Effects

Pioglitazone

Clinical studies demonstrate that pioglitazone improves insulin sensitivity in insulin-resistant patients. Pioglitazone enhances cellular responsiveness to insulin, increases insulin-dependent glucose disposal, improves hepatic sensitivity to insulin, and improves dysfunctional glucose homeostasis. In patients with type 2 diabetes, the decreased insulin resistance produced by pioglitazone results in lower plasma glucose concentrations, lower plasma insulin levels, and lower A1C values. Based on results from an open-label extension study, the glucose-lowering effects of pioglitazone appear to persist for at least one year. In controlled clinical studies, pioglitazone in combination with a sulfonylurea had an additive effect on glycemic control.

Patients with lipid abnormalities were included in placebo-controlled monotherapy clinical studies with pioglitazone. Overall, patients treated with pioglitazone had mean decreases in triglycerides, mean increases in HDL cholesterol, and no consistent mean changes in LDL cholesterol and total cholesterol compared to the placebo group. A similar pattern of results was seen in 16-week and 24-week combination therapy studies of pioglitazone with a sulfonylurea.

Glimepiride

A mild glucose-lowering effect first appeared following single oral doses as low as 0.5 to 0.6 mg in healthy subjects. The time required to reach the maximum effect (i.e., minimum blood glucose level [T_{\min}]) was about two to three hours. In patients with type 2 diabetes, both fasting and 2-hour postprandial glucose levels were significantly lower with glimepiride (1, 2, 4 and 8 mg once daily) than with placebo after 14 days of oral dosing. The glucose-lowering effect in all active treatment groups was maintained over 24 hours.

In larger dose-ranging studies, blood glucose and A1C were found to respond in a dose-dependent manner over the range of 1 to 4 mg/day of glimepiride. Some patients, particularly those with higher fasting plasma glucose (FPG) levels, may benefit from doses of glimepiride up to 8 mg once daily. No difference in response was found when glimepiride was administered once or twice daily.

In two 14-week, placebo-controlled studies in 720 subjects, the average net reduction in A1C for patients treated with 8 mg of glimepiride once daily was 2.0% in absolute units compared with placebo-treated patients. In a long-term, randomized, placebo-controlled study of patients with type 2 diabetes unresponsive to dietary management, glimepiride therapy improved postprandial insulin/C-peptide responses, and 75% of patients achieved and maintained control of blood glucose and A1C. Efficacy results were not affected by age, gender, weight or race. In long-term extension trials with previously treated patients, no meaningful deterioration in mean fasting plasma glucose (FPG) or A1C levels was seen after 2 1/2 years of glimepiride therapy.

Glimepiride therapy is effective in controlling blood glucose without deleterious changes in the plasma lipoprotein profiles of patients treated for type 2 diabetes.

Clinical Studies

There have been no clinical efficacy studies conducted with DUETACT. However, the efficacy and safety of the separate components have been previously established. The coadministration of pioglitazone and a sulfonylurea, including glimepiride, has been evaluated for efficacy and safety in two clinical studies. These clinical studies established an added benefit of pioglitazone in glycemic control of patients with inadequately controlled type 2 diabetes while on sulfonylurea therapy. Bioequivalence of DUETACT with coadministered pioglitazone and glimepiride tablets was demonstrated at the 30 mg/2 mg and 30 mg/4 mg dosage strengths (see **CLINICAL PHARMACOLOGY, Pharmacokinetics and Drug Metabolism, Absorption and Bioavailability**).

Clinical Studies of Pioglitazone Add-on Therapy in Patients Not Adequately Controlled on a Sulfonylurea

Two treatment-randomized, controlled clinical studies in patients with type 2 diabetes were conducted to evaluate the safety and efficacy of pioglitazone plus a sulfonylurea.

Both studies included patients receiving a sulfonylurea, either alone or in combination with another antihyperglycemic agent, who had inadequate glycemic control. Excluding the sulfonylurea agent, all other antihyperglycemic agents were discontinued prior to starting study treatment. In the first study, 560 patients were randomized to receive 15 mg or 30 mg of pioglitazone or placebo once daily in addition to their current sulfonylurea regimen for 16 weeks. In the second study, 702 patients were randomized to receive 30 mg or 45 mg of pioglitazone once daily in addition to their current sulfonylurea regimen for 24 weeks.

In the first study, the addition of pioglitazone 15 mg or 30 mg once daily to treatment with a sulfonylurea after 16 weeks significantly reduced the mean A1C by 0.88% and 1.28% and the mean FPG by 39.4 mg/dL and 57.9 mg/dL, respectively, from that observed with sulfonylurea treatment alone. In the second study, the mean reductions from baseline at Week 24 in A1C were 1.55% and 1.67% for the 30 mg and 45 mg doses, respectively. Mean reductions from baseline in FPG were 51.5 mg/dL and 56.1 mg/dL, respectively. Based on these reductions in A1C and FPG (*Table 2*), the addition of pioglitazone to sulfonylurea resulted in significant improvements in glycemic control irrespective of the sulfonylurea dosage.

Table 2. Glycemic Parameters in 16-Week and 24-Week Pioglitazone + Sulfonylurea Combination Studies

Parameter	Placebo + Sulfonylurea	Pioglitazone 15 mg + Sulfonylurea	Pioglitazone 30 mg + Sulfonylurea
16-Week Study			
A1C (%)	N=181	N=176	N=182
Baseline mean	9.86	10.01	9.93
Mean change from baseline at 16 weeks	0.06	-0.82 ^{*,†}	-1.22 ^{*,†}
Difference in change from placebo + sulfonylurea		-0.88	-1.28
Responder rate (%)[‡]	23.8	56.8	74.2
FPG (mg/dL)	N=182	N=179	N=186
Baseline mean	236	246.8	238.9
Mean change from baseline at 16 weeks	5.6	-33.8 ^{*,†}	-52.3 ^{*,†}
Difference in change from placebo + sulfonylurea		-39.4	-57.9
Responder rate (%)[§]	22.0	55.3	67.7
24-Week Study			
A1C (%)	N=340	N=332	
Baseline mean	9.77	9.85	
Mean change from baseline at 24 weeks	-1.55 [*]	-1.67 [*]	
Responder rate (%)[‡]	77.4	79.5	
FPG (mg/dL)	N=338	N=329	
Baseline mean	214.4	217.2	
Mean change from baseline at 24 weeks	-51.5 [*]	-56.1 [*]	
Responder rate (%)[§]	63.6	71.1	

*significant change from baseline $p \leq 0.050$

†significant difference from placebo plus sulfonylurea, $p \leq 0.050$

‡patients who achieved an A1C $\leq 6.1\%$ or $\geq 0.6\%$ decrease from baseline

§patients who achieved a decrease in FPG by ≥ 30 mg/dL

INDICATIONS AND USAGE

DUETACT is a thiazolidinedione and sulfonylurea combination product indicated as an adjunct to diet and exercise to improve glycemic control in adults with type 2 diabetes mellitus who are already treated with a thiazolidinedione and a sulfonylurea or who have inadequate glycemic control on a thiazolidinedione alone or a sulfonylurea alone.

CONTRAINDICATIONS

Initiation of DUETACT in patients with established New York Heart Association (NYHA) Class III or IV heart failure is contraindicated (see **BOXED WARNING**).

In addition, DUETACT is contraindicated in patients with:

1. Known hypersensitivity to pioglitazone, glimepiride or any other component of DUETACT.
2. Diabetic ketoacidosis, with or without coma. This condition should be treated with insulin.

WARNINGS

Glimepiride

SPECIAL WARNING ON INCREASED RISK OF CARDIOVASCULAR MORTALITY

The administration of oral hypoglycemic drugs has been reported to be associated with increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. This warning is based on the study conducted by the University Group Diabetes Program (UGDP), a long-term, prospective clinical trial designed to evaluate the effectiveness of glucose-lowering drugs in preventing or delaying vascular complications in patients with non-insulin-dependent diabetes. The study involved 823 patients who were randomly assigned to one of four treatment groups (Diabetes, 19 supp. 2: 747-830, 1970).

UGDP reported that patients treated for five to eight years with diet plus a fixed dose of tolbutamide (1.5 g/day) had a rate of cardiovascular mortality approximately 2-1/2 times that of patients treated with diet alone. A significant increase in total mortality was not observed, but the use of tolbutamide was discontinued based on the increase in cardiovascular mortality, thus limiting the opportunity for the study to show an increase in overall mortality. Despite controversy regarding the interpretation of these results, the findings of the UGDP study provide an adequate basis for this warning. The patient should be informed of the potential risks and advantages of glimepiride tablets and of alternative modes of therapy.

Although only one drug in the sulfonylurea class (tolbutamide) was included in this study, it is prudent from a safety standpoint to consider that this warning may also apply to other oral hypoglycemic drugs in this class, in view of their close similarities in mode of action and chemical structure.

Pioglitazone

Cardiac Failure and Other Cardiac Effects

Pioglitazone, like other thiazolidinediones, can cause fluid retention when used alone or in combination with other antidiabetic agents, including insulin. Fluid retention may lead to or exacerbate heart failure. Patients should be observed for signs and symptoms of heart failure. If these signs and symptoms develop, the heart failure should be managed according to current standards of care. Furthermore, discontinuation or dose reduction of pioglitazone must be considered. Patients with NYHA Class III and IV cardiac status were not studied during preapproval clinical trials and pioglitazone is not recommended in these patients (see **BOXED WARNING** and **CONTRAINDICATIONS**).

In one 16-week U.S. double-blind, placebo-controlled clinical trial involving 566 patients with type 2 diabetes, pioglitazone at doses of 15 mg and 30 mg in combination with insulin was compared to insulin therapy alone. This trial included patients with long-standing diabetes and a high prevalence of pre-existing medical conditions as follows: arterial hypertension (57.2%), peripheral neuropathy (22.6%), coronary heart disease (19.6%), retinopathy (13.1%), myocardial infarction (8.8%), vascular disease (6.4%), angina pectoris (4.4%), stroke and/or transient ischemic attack (4.1%) and congestive heart failure (2.3%).

In this study, two of the 191 patients receiving 15 mg pioglitazone plus insulin (1.1%) and two of the 188 patients receiving 30 mg pioglitazone plus insulin (1.1%) developed congestive heart failure compared with none of the 187 patients on insulin therapy alone. All four of these patients had previous histories of cardiovascular conditions, including coronary artery disease, previous CABG procedures and myocardial infarction. In a 24-week dose-controlled study in which pioglitazone was coadministered with insulin, 0.3% of patients (1/345) on 30 mg and 0.9% (3/345) of patients on 45 mg reported CHF as a serious adverse event.

Analysis of data from these studies did not identify specific factors that predict increased risk of congestive heart failure on combination therapy with insulin.

In Type 2 Diabetes and Congestive Heart Failure (Systolic Dysfunction)

A 24-week post-marketing safety study was performed to compare pioglitazone (n=262) to glyburide (n=256) in uncontrolled diabetic patients (mean A1C 8.8% at baseline) with NYHA Class II and III heart failure and ejection fraction less than 40% (mean EF 30% at baseline). Over the course of the study, overnight hospitalization for congestive heart failure was reported in 9.9% of patients on pioglitazone compared to 4.7% of patients on glyburide with a treatment difference observed from six weeks. This adverse event associated with pioglitazone was more marked in patients using insulin at baseline and in patients over 64 years of age. No difference in cardiovascular mortality between the treatment groups was observed.

Pioglitazone should be initiated at the lowest approved dose if it is prescribed for patients with type 2 diabetes and systolic heart failure (NYHA Class II). If subsequent dose escalation is necessary, the dose should be increased gradually only after several months of treatment with careful monitoring for weight gain, edema or signs and symptoms of CHF exacerbation (see **DOSAGE AND ADMINISTRATION, Special Patient Populations**).

Prospective Pioglitazone Clinical Trial in Macrovascular Events (PROactive)

In PROactive, 5238 patients with type 2 diabetes and a prior history of macrovascular disease were treated with ACTOS (n=2605), force-titrated up to 45 mg once daily, or placebo (n=2633) (see **ADVERSE REACTIONS**). The percentage of patients who had an event of serious heart failure was higher for patients treated with ACTOS (5.7%, n=149) than for patients treated with placebo (4.1%, n=108). The incidence of death subsequent to a report of serious heart failure was 1.5% (n=40) in patients treated with ACTOS and 1.4% (n=37) in placebo-treated patients. In patients treated with an insulin-containing regimen at baseline, the incidence of serious heart failure was 6.3% (n=54/864) with ACTOS and 5.2% (n=47/896) with placebo. For those patients treated with a sulfonylurea-containing regimen at baseline, the incidence of serious heart failure was 5.8% (n=94/1624) with ACTOS and 4.4% (n=71/1626) with placebo.

PRECAUTIONS**General****Pioglitazone**

Pioglitazone exerts its antihyperglycemic effect only in the presence of insulin. Therefore, DUETACT should not be used in patients with type 1 diabetes or for the treatment of diabetic ketoacidosis.

Hypoglycemia

Patients receiving pioglitazone in combination with insulin or oral hypoglycemic agents may be at risk for hypoglycemia, and a reduction in the dose of the concomitant agent may be necessary.

Cardiovascular

In U.S. placebo-controlled clinical trials that excluded patients with New York Heart Association (NYHA) Class III and IV cardiac status, the incidence of serious cardiac adverse events related to volume expansion was not increased in patients treated with pioglitazone as monotherapy or in combination with sulfonylureas or metformin versus placebo-treated patients. In insulin combination studies, a small number of patients with a history of previously existing cardiac disease developed congestive heart failure when treated with pioglitazone in combination with insulin (see **WARNINGS, Pioglitazone, Cardiac Failure and Other Cardiac Effects**). Patients with NYHA Class III and IV cardiac status were not studied in pre-approval pioglitazone clinical trials. Pioglitazone is not indicated in patients with NYHA Class III or IV cardiac status.

In postmarketing experience with pioglitazone, cases of congestive heart failure have been reported in patients both with and without previously known heart disease.

Edema

In all U.S. clinical trials with pioglitazone, edema was reported more frequently in patients treated with pioglitazone than in placebo-treated patients and appears to be dose-related (see **ADVERSE REACTIONS, Pioglitazone**). In postmarketing experience, reports of initiation or worsening of edema have been received. Since thiazolidinediones, including pioglitazone, can cause fluid retention, which can exacerbate or lead to congestive heart failure, DUETACT should be used with caution in patients at risk for heart failure. Patients should be monitored for signs and symptoms of

heart failure (see **BOXED WARNING, WARNINGS, Pioglitazone, and PRECAUTIONS, Information for Patients**).

Weight Gain

Dose-related weight gain was observed with pioglitazone alone and in combination with other hypoglycemic agents (*Table 3*). The mechanism of weight gain is unclear but probably involves a combination of fluid retention and fat accumulation.

Table 3. Weight Changes (kg) from Baseline During Double-Blind Clinical Trials with Pioglitazone

		Control Group (Placebo)	Pioglitazone 15 mg	Pioglitazone 30 mg	Pioglitazone 45 mg
		Median (25 th /75 th percentile)			
Monotherapy		-1.4 (-2.7/0.0) n=256	0.9 (-0.5/3.4) n = 79	1.0 (-0.9/3.4) n=188	2.6 (0.2/5.4) n = 79
Combination Therapy	Sulfonylurea	-0.5 (-1.8/0.7) n=187	2.0 (0.2/3.2) n=183	3.1 (1.1/5.4) n=528	4.1 (1.8/7.3) n=333
	Metformin	-1.4 (-3.2/0.3) n=160	N/A	0.9 (-0.3/3.2) n=567	1.8 (-0.9/5.0) n=407
	Insulin	0.2 (-1.4/1.4) n=182	2.3 (0.5/4.3) n=190	3.3 (0.9/6.3) n=522	4.1 (1.4/6.8) n=338

Note: Trial durations of 16 to 26 weeks

Urinary Bladder Tumors

Tumors were observed in the urinary bladder of male rats in the two-year carcinogenicity study (see **Carcinogenesis, Mutagenesis and Impairment of Fertility, Pioglitazone**). In two 3-year trials in which ACTOS was compared to placebo or glyburide, there were 16/3656 (0.44%) reports of bladder cancer in patients taking ACTOS compared to 5/3679 (0.14%) in patients not taking ACTOS. After excluding patients in whom exposure to study drug was less than one year at the time of diagnosis of bladder cancer, there were six (0.16%) cases on ACTOS and two (0.05%) cases on placebo.

A five-year interim report of an ongoing 10-year observational cohort study found a nonsignificant increase in the risk for bladder cancer in subjects ever exposed to ACTOS, compared to subjects never exposed to ACTOS (HR 1.2 [95% CI 0.9 – 1.5]). Compared to never exposure, a duration of ACTOS therapy longer than 12 months was associated with an increase in risk (HR 1.4 [95% CI 0.9 – 2.1]), which reached statistical significance after more than 24 months of ACTOS use (HR 1.4 [95% CI 1.03 – 2.0]). Interim results from this study suggested that taking pioglitazone longer than 12 months increased the relative risk of developing bladder cancer in any given year by 40% which equates to an absolute increase of three cases in 10,000 (from approximately seven in 10,000 [without ACTOS] to approximately 10 in 10,000 [with ACTOS]).

There are insufficient data to determine whether pioglitazone is a tumor promoter for urinary bladder tumors. Consequently, DUETACT should not be used in patients with active bladder cancer and the benefits of glycemic control versus unknown risks for cancer recurrence with DUETACT should be considered in patients with a prior history of bladder cancer.

Ovulation

Therapy with pioglitazone, like other thiazolidinediones, may result in ovulation in some premenopausal anovulatory women. Thus, adequate contraception in premenopausal women should be recommended while taking DUETACT. This possible effect has not been investigated in clinical studies so the frequency of this occurrence is not known.

Hematologic

Across all clinical studies with pioglitazone, mean hemoglobin values declined by 2% to 4% in patients treated with pioglitazone. These changes primarily occurred within the first four to 12 weeks of therapy and remained relatively constant thereafter. These changes may be related to increased plasma volume and have rarely been associated with any significant hematologic clinical effects (see **ADVERSE REACTIONS, Laboratory Abnormalities, Pioglitazone, Hematologic**). DUETACT may cause decreases in hemoglobin and hematocrit.

Hepatic Effects

In preapproval clinical studies worldwide, over 4500 subjects were treated with pioglitazone. In U.S. clinical studies, over 4700 patients with type 2 diabetes received pioglitazone. There was no evidence of drug-induced hepatotoxicity or elevation of ALT levels in the clinical studies.

During preapproval placebo-controlled clinical trials in the U.S., a total of four of 1526 (0.26%) patients treated with pioglitazone and two of 793 (0.25%) placebo-treated patients had ALT values ≥ 3 times the upper limit of normal. The ALT elevations in patients treated with pioglitazone were reversible and were not clearly related to therapy with pioglitazone.

In postmarketing experience with pioglitazone, reports of hepatitis and of hepatic enzyme elevations to three or more times the upper limit of normal have been received. Very rarely, these reports have involved hepatic failure with and without fatal outcome, although causality has not been established.

Pending the availability of the results of additional large, long-term controlled clinical trials and additional postmarketing safety data on pioglitazone, it is recommended that patients treated with DUETACT undergo periodic monitoring of liver enzymes.

Serum ALT (alanine aminotransferase) levels should be evaluated prior to the initiation of therapy with DUETACT in all patients and periodically thereafter per the clinical judgment of the health care professional. Liver function tests should also be obtained for patients if symptoms suggestive of hepatic dysfunction occur, e.g., nausea, vomiting, abdominal pain, fatigue, anorexia, or dark urine. The decision whether to continue the patient on therapy with DUETACT should be guided by clinical judgment pending laboratory evaluations. If jaundice is observed, drug therapy should be discontinued.

Therapy with DUETACT should not be initiated if the patient exhibits clinical evidence of active liver disease or the ALT levels exceed 2.5 times the upper limit of normal.

Patients with mildly elevated liver enzymes (ALT levels at 1 to 2.5 times the upper limit of normal) at baseline or anytime during therapy with DUETACT should be evaluated to determine the cause of the liver enzyme elevation. Initiation or continuation of therapy with DUETACT in patients with mildly elevated liver enzymes should proceed with caution and include appropriate clinical follow-up, which may include more frequent liver enzyme monitoring. If serum transaminase levels are increased (ALT >2.5 times the upper limit of normal), liver function tests should be evaluated more frequently until the levels return to normal or pretreatment values. If ALT levels exceed three times the upper limit of normal, the test should be repeated as soon as possible. If ALT levels remain >3 times the upper limit of normal or if the patient is jaundiced, DUETACT therapy should be discontinued.

Macular Edema

Macular edema has been reported in postmarketing experience in diabetic patients who were taking pioglitazone or another thiazolidinedione. Some patients presented with blurred vision or decreased visual acuity, but some patients appear to have been diagnosed on routine ophthalmologic examination. Some patients had peripheral edema at the time macular edema was diagnosed. Some patients had improvement in their macular edema after discontinuation of their thiazolidinedione. It is unknown whether or not there is a causal relationship between pioglitazone and macular edema. Patients with diabetes should have regular eye exams by an ophthalmologist, per the Standards of Care of the American Diabetes Association. Additionally, any diabetic who reports any kind of visual symptom should be promptly referred to an ophthalmologist, regardless of the patient's underlying medications or other physical findings (see **ADVERSE REACTIONS**).

Fractures

In a randomized trial (PROactive) in patients with type 2 diabetes (mean duration of diabetes 9.5 years), an increased incidence of bone fracture was noted in female patients taking pioglitazone. During a mean follow-up of 34.5 months, the incidence of bone fracture in females was 5.1% (44/870) for pioglitazone versus 2.5% (23/905) for placebo. This difference was noted after the first year of treatment and remained during the course of the study. The majority of fractures observed in female patients were nonvertebral fractures, including lower limb and distal upper limb. No increase in fracture rates was observed in men treated with pioglitazone 1.7% (30/1735) versus placebo 2.1% (37/1728). The risk of fracture should be considered in the care of patients, especially female patients, treated with pioglitazone, and attention should be given to assessing and maintaining bone health according to current standards of care.

Macrovascular Outcomes

There have been no clinical studies establishing conclusive evidence of macrovascular risk reduction with DUETACT or any other antidiabetic drug.

General

Glimepiride

Hypoglycemia

All sulfonylurea drugs are capable of producing severe hypoglycemia. Proper patient selection, dosage and instructions are important to avoid hypoglycemic episodes. Patients with impaired renal function may be more sensitive to the glucose-lowering effect of glimepiride. A starting dose of 1 mg of glimepiride once daily followed by

appropriate dose titration is recommended in those patients (see **DOSAGE AND ADMINISTRATION, Special Patient Populations**). Debilitated or malnourished patients, and those with adrenal, pituitary or hepatic insufficiency are particularly susceptible to the hypoglycemic action of glucose-lowering drugs. Hypoglycemia may be difficult to recognize in the elderly and in people who are taking beta-adrenergic blocking drugs or other sympatholytic agents. Hypoglycemia is more likely to occur when caloric intake is deficient, after severe or prolonged exercise, when alcohol is ingested or when more than one glucose-lowering drug is used. Combined use of glimepiride with insulin or metformin may increase the potential for hypoglycemia.

Loss of Control of Blood Glucose

When a patient stabilized on any diabetic regimen is exposed to stress such as fever, trauma, infection, or surgery, a loss of control may occur. The effectiveness of any oral hypoglycemic drug, including DUETACT, in lowering blood glucose to a desired level decreases in many patients over a period of time, which may be due to progression of the severity of the diabetes or to diminished responsiveness to the drug.

Hemolytic Anemia

Treatment of patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency with sulfonylurea agents can lead to hemolytic anemia. Because DUETACT contains glimepiride, which belongs to the class of sulfonylurea agents, caution should be used in patients with G6PD deficiency and a non-sulfonylurea alternative should be considered. In postmarketing reports, hemolytic anemia has also been reported in patients who did not have known G6PD deficiency.

Laboratory Tests

FPG and A1C measurements should be performed periodically to monitor glycemic control and therapeutic response to DUETACT.

Liver enzyme monitoring is recommended prior to initiation of therapy with DUETACT in all patients and periodically thereafter per the clinical judgment of the health care professional (see **PRECAUTIONS, General, Pioglitazone, Hepatic Effects** and **ADVERSE REACTIONS, Laboratory Abnormalities, Pioglitazone, Serum Transaminase Levels**).

Information for Patients

Patients should be instructed regarding the importance of adhering to dietary instructions, a regular exercise program and regular testing of blood glucose and A1C. During periods of stress such as fever, trauma, infection or surgery, medication requirements may change and patients should be reminded to seek medical advice promptly. Patients should also be informed of the potential risks and advantages of DUETACT and of alternative modes of therapy.

Prior to initiation of DUETACT therapy, the risks of hypoglycemia, its symptoms and treatment, and conditions that predispose to its development should be explained to patients and responsible family members (see **PRECAUTIONS, General, Pioglitazone** and **Glimepiride, Hypoglycemia**). Combination therapy of DUETACT with other antihyperglycemic agents may also cause hypoglycemia.

Patients who experience an unusually rapid increase in weight or edema or who develop shortness of breath or other symptoms of heart failure while on DUETACT should immediately report these symptoms to their physician.

Patients should be told that blood tests for liver function will be performed prior to the start of therapy and periodically thereafter per the clinical judgment of the health-care professional. Patients should be told to seek immediate medical advice for unexplained nausea, vomiting, abdominal pain, fatigue, anorexia or dark urine.

Therapy with a thiazolidinedione, including the active pioglitazone component of the DUETACT tablet, may result in ovulation in some premenopausal anovulatory women. As a result, these patients may be at an increased risk for pregnancy while taking DUETACT. This possible effect has not been investigated in clinical studies so the frequency of this occurrence is not known. Thus, adequate contraception in premenopausal women should be recommended. Patients who become pregnant while on DUETACT or are planning a pregnancy should be advised to discuss with their physician a regimen appropriate for maintaining adequate glycemic control (see **PRECAUTIONS, Pregnancy: Pregnancy Category C**).

Patients should be told to promptly report any sign of macroscopic hematuria or other symptoms such as dysuria or urinary urgency that develop or increase during treatment as these may be due to bladder cancer.

Patients should be told to take a single dose of DUETACT once daily with the first main meal and instructed that any change in dosing should be made only if directed by their physician (see **DOSAGE AND ADMINISTRATION, Maximum Recommended Dose**).

Drug Interactions

Pioglitazone

In vivo drug-drug interaction studies have suggested that pioglitazone may be a weak inducer of CYP 450 isoform 3A4 substrate.

An enzyme inhibitor of CYP2C8 (such as gemfibrozil) may significantly increase the AUC of pioglitazone and an enzyme inducer of CYP2C8 (such as rifampin) may significantly decrease the AUC of pioglitazone. Therefore, if an inhibitor or inducer of CYP2C8 is started or stopped during treatment with pioglitazone, changes in diabetes treatment may be needed based on clinical response (see **CLINICAL PHARMACOLOGY, Drug-Drug Interactions, Pioglitazone**).

Glimepiride

(See **CLINICAL PHARMACOLOGY, Drug-Drug Interactions, Glimepiride**)

Carcinogenesis, Mutagenesis, Impairment of Fertility

DUETACT

No animal studies have been conducted with DUETACT. The following data are based on findings in studies performed with pioglitazone or glimepiride individually.

Pioglitazone

A two-year carcinogenicity study was conducted in male and female rats at oral doses up to 63 mg/kg (approximately 14 times the maximum recommended human oral dose of 45 mg based on mg/m²). Drug-induced tumors were not observed in any organ except for the urinary bladder. Benign and/or malignant transitional cell neoplasms were observed in male rats at 4 mg/kg/day and above (approximately equal to the maximum

recommended human oral dose based on mg/m^2). A two-year carcinogenicity study was conducted in male and female mice at oral doses up to 100 $\text{mg}/\text{kg}/\text{day}$ (approximately 11 times the maximum recommended human oral dose based on mg/m^2). No drug-induced tumors were observed in any organ.

Pioglitazone was not mutagenic in a battery of genetic toxicology studies, including the Ames bacterial assay, a mammalian cell forward gene mutation assay (CHO/HPRT and AS52/XPRT), an *in vitro* cytogenetics assay using CHL cells, an unscheduled DNA synthesis assay and an *in vivo* micronucleus assay.

No adverse effects upon fertility were observed in male and female rats at oral doses up to 40 mg/kg pioglitazone daily prior to and throughout mating and gestation (approximately nine times the maximum recommended human oral dose based on mg/m^2).

Glimepiride

Studies in rats at doses of up to 5000 ppm in complete feed (approximately 340 times the maximum recommended human dose, based on surface area) for 30 months showed no evidence of carcinogenesis. In mice, administration of glimepiride for 24 months resulted in an increase in benign pancreatic adenoma formation which was dose related and is thought to be the result of chronic pancreatic stimulation. The no-effect dose for adenoma formation in mice in this study was 320 ppm in complete feed, or 46 to 54 mg/kg body weight/day. This is about 35 times the maximum human recommended dose of 8 mg once daily based on surface area.

Glimepiride was nonmutagenic in a battery of *in vitro* and *in vivo* mutagenicity studies (Ames test, somatic cell mutation, chromosomal aberration, unscheduled DNA synthesis, mouse micronucleus test).

There was no effect of glimepiride on male mouse fertility in animals exposed up to 2500 mg/kg body weight (>1700 times the maximum recommended human dose based on surface area). Glimepiride had no effect on the fertility of male and female rats administered up to 4000 mg/kg body weight (approximately 4000 times the maximum recommended human dose based on surface area).

Animal Toxicology

Pioglitazone

Heart enlargement has been observed in mice (100 mg/kg), rats (4 mg/kg and above) and dogs (3 mg/kg) treated orally with pioglitazone hydrochloride (approximately 11, 1, and 2 times the maximum recommended human oral dose for mice, rats and dogs, respectively, based on mg/m^2). In a one-year rat study, drug-related early death due to apparent heart dysfunction occurred at an oral dose of 160 $\text{mg}/\text{kg}/\text{day}$ (approximately 35 times the maximum recommended human oral dose based on mg/m^2). Heart enlargement was seen in a 13-week study in monkeys at oral doses of 8.9 mg/kg and above (approximately four times the maximum recommended human oral dose based on mg/m^2), but not in a 52-week study at oral doses up to 32 mg/kg (approximately 13 times the maximum recommended human oral dose based on mg/m^2).

Glimepiride

Reduced serum glucose values and degranulation of the pancreatic beta cells were observed in beagle dogs exposed to 320 mg glimepiride/kg/day for 12 months (approximately 1000 times the recommended human dose based on surface area). No evidence of tumor formation was observed in any organ. One female and one male dog developed bilateral subcapsular cataracts. Non-GLP studies indicated that glimepiride was unlikely to exacerbate cataract formation. Evaluation of the cocataractogenic potential of glimepiride in several diabetic and cataract rat models was negative and there was no adverse effect of glimepiride on bovine ocular lens metabolism in organ culture.

Pregnancy: Pregnancy Category C**DUETACT**

Because current information strongly suggests that abnormal blood glucose levels during pregnancy are associated with a higher incidence of congenital anomalies, as well as increased neonatal morbidity and mortality, most experts recommend that insulin be used during pregnancy to maintain blood glucose levels as close to normal as possible. DUETACT should not be used during pregnancy unless the potential benefit justifies the potential risk to the fetus.

There are no adequate and well-controlled studies in pregnant women with DUETACT or its individual components. No animal studies have been conducted with the combined products in DUETACT. The following data are based on findings in studies performed with pioglitazone or glimepiride individually.

Pioglitazone

Pioglitazone was not teratogenic in rats at oral doses up to 80 mg/kg or in rabbits given up to 160 mg/kg during organogenesis (approximately 17 and 40 times the maximum recommended human oral dose based on mg/m^2 , respectively). Delayed parturition and embryotoxicity (as evidenced by increased postimplantation losses, delayed development and reduced fetal weights) were observed in rats at oral doses of 40 mg/kg/day and above (approximately 10 times the maximum recommended human oral dose based on mg/m^2). No functional or behavioral toxicity was observed in offspring of rats. In rabbits, embryotoxicity was observed at an oral dose of 160 mg/kg (approximately 40 times the maximum recommended human oral dose based on mg/m^2). Delayed postnatal development, attributed to decreased body weight, was observed in offspring of rats at oral doses of 10 mg/kg and above during late gestation and lactation periods (approximately two times the maximum recommended human oral dose based on mg/m^2).

Glimepiride***Teratogenic Effects***

Glimepiride did not produce teratogenic effects in rats exposed orally up to 4000 mg/kg body weight (approximately 4,000 times the maximum recommended human dose based on surface area) or in rabbits exposed up to 32 mg/kg body weight (approximately 60 times the maximum recommended human dose based on surface area). Glimepiride has been shown to be associated with intrauterine fetal death in rats when given in doses as low as 50 times the human dose based on surface area and in rabbits when given in doses as low as 0.1 times the human dose based on surface area. This fetotoxicity, observed only at doses inducing maternal hypoglycemia, has

been similarly noted with other sulfonylureas and is believed to be directly related to the pharmacologic (hypoglycemic) action of glimepiride.

Nonteratogenic Effects

In some studies in rats, offspring of dams exposed to high levels of glimepiride during pregnancy and lactation developed skeletal deformities consisting of shortening, thickening, and bending of the humerus during the postnatal period. Significant concentrations of glimepiride were observed in the serum and breast milk of the dams as well as in the serum of the pups. These skeletal deformations were determined to be the result of nursing from mothers exposed to glimepiride.

Prolonged severe hypoglycemia (four to 10 days) has been reported in neonates born to mothers who were receiving a sulfonylurea drug at the time of delivery. This has been reported more frequently with the use of agents with prolonged half-lives. Patients who are planning a pregnancy should consult their physician, and it is recommended that they change over to insulin for the entire course of pregnancy and lactation.

Nursing Mothers

No studies have been conducted with the combined components of DUETACT. In studies performed with the individual components, pioglitazone was secreted in the milk of lactating rats and significant concentrations of glimepiride were observed in the serum and breast milk of the dams and serum of the pups. It is not known whether pioglitazone or glimepiride are secreted in human milk. However, other sulfonylureas are excreted in human milk. Because the potential for hypoglycemia in nursing infants may exist, and because of the effects on nursing animals, DUETACT should not be administered to a woman breastfeeding. If DUETACT is discontinued, and if diet alone is inadequate for controlling blood glucose, insulin therapy should be considered (see **PRECAUTIONS, Pregnancy: Pregnancy Category C, Glimepiride, *Nonteratogenic Effects***).

Pediatric Use

Safety and effectiveness of DUETACT in pediatric patients have not been established.

Elderly Use

Pioglitazone

Approximately 500 patients in placebo-controlled clinical trials of pioglitazone were 65 and over. No significant differences in effectiveness and safety were observed between these patients and younger patients.

Glimepiride

In U.S. clinical studies of glimepiride, 608 of 1986 patients were 65 and over. No overall differences in safety or effectiveness were observed between these subjects and younger subjects, but greater sensitivity of some older individuals cannot be ruled out.

Comparison of glimepiride pharmacokinetics in patients with type 2 diabetes ≤ 65 years ($n=49$) and those >65 years ($n=42$) was performed in a study using a dosing regimen of 6 mg daily. There were no significant differences in glimepiride pharmacokinetics between the two age groups (see **CLINICAL PHARMACOLOGY, Special Populations, Elderly, *Glimepiride***).

Glimepiride is known to be substantially excreted by the kidney, and the risk of toxic reactions to this drug may be greater in patients with impaired renal function. Because

elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function.

Elderly patients are particularly susceptible to hypoglycemic action of glucose-lowering drugs. In elderly, debilitated or malnourished patients, or in patients with renal and hepatic insufficiency, the initial dosing, dose increments and maintenance dosage should be conservative based upon blood glucose levels prior to and after initiation of treatment to avoid hypoglycemic reactions. Hypoglycemia may be difficult to recognize in the elderly and in people who are taking beta-adrenergic blocking drugs or other sympatholytic agents (see **CLINICAL PHARMACOLOGY, Special Populations, Renal Insufficiency: *Glimepiride*; PRECAUTIONS, General: *Glimepiride*, Hypoglycemia and DOSAGE AND ADMINISTRATION, Special Patient Populations**).

ADVERSE REACTIONS

The adverse events reported in at least 5% of patients in the controlled 16-week clinical studies between placebo plus a sulfonylurea and pioglitazone (15 mg and 30 mg combined) plus sulfonylurea-treatment arms were upper respiratory tract infection (15.5% and 16.6%), accidental injury (8.6% and 3.5%) and combined edema/peripheral edema (2.1% and 7.2%), respectively.

The incidence and type of adverse events reported in at least 5% of patients in any combined treatment group from the 24-week study comparing pioglitazone 30 mg plus a sulfonylurea and pioglitazone 45 mg plus a sulfonylurea are shown in *Table 4*; the rate of adverse events resulting in study discontinuation between the two treatment groups was 6.0% and 9.7%, respectively.

Table 4. Adverse Events That Occurred in $\geq 5\%$ of Patients in Any Treatment Group During the 24-Week Study

Adverse Event	Pioglitazone 30 mg + Sulfonylurea N=351 n (%)	Pioglitazone 45 mg + Sulfonylurea N=351 n (%)
Hypoglycemia	47 (13.4)	55 (15.7)
Upper Respiratory Tract Infection	43 (12.3)	52 (14.8)
Weight Increased	32 (9.1)	47 (13.4)
Edema Lower Limb	20 (5.7)	43 (12.3)
Headache	25 (7.1)	14 (4.0)
Urinary Tract Infection	20 (5.7)	24 (6.8)
Diarrhea	21 (6.0)	15 (4.3)
Nausea	18 (5.1)	14 (4.0)
Pain in Limb	19 (5.4)	14 (4.0)

In U.S. double-blind studies, anemia was reported in $\leq 2\%$ of patients treated with pioglitazone plus a sulfonylurea (see **PRECAUTIONS, General, Pioglitazone**).

Pioglitazone

Over 8500 patients with type 2 diabetes have been treated with pioglitazone in randomized, double-blind, controlled clinical trials. This includes 2605 high-risk patients

with type 2 diabetes treated with pioglitazone from the PROactive clinical trial. Over 6000 patients have been treated for six months or longer and over 4500 patients for one year or longer. Over 3000 patients have received pioglitazone for at least two years.

Most clinical adverse events were similar between groups treated with pioglitazone in combination with a sulfonylurea and those treated with pioglitazone monotherapy. Other adverse events reported in at least 5% of patients in controlled clinical studies between placebo and pioglitazone monotherapy included myalgia (2.7% and 5.4%), tooth disorder (2.3% and 5.3%), diabetes mellitus aggravated (8.1% and 5.1%) and pharyngitis (0.8% and 5.1%), respectively.

In monotherapy studies, edema was reported for 4.8% (with doses from 7.5 mg to 45 mg) of patients treated with pioglitazone versus 1.2% of placebo-treated patients. Most of these events were considered mild or moderate in intensity (see **PRECAUTIONS, General, Pioglitazone, Edema**).

Prospective Pioglitazone Clinical Trial in Macrovascular Events (PROactive)

In PROactive, 5238 patients with type 2 diabetes and a prior history of macrovascular disease were treated with ACTOS (n=2605), force-titrated up to 45 mg daily, or placebo (n=2633), in addition to standard of care. Almost all subjects (95%) were receiving cardiovascular medications (beta blockers, ACE inhibitors, ARBs, calcium channel blockers, nitrates, diuretics, aspirin, statins, fibrates). Patients had a mean age of 61.8 years, mean duration of diabetes 9.5 years, and mean A1C 8.1%. Average duration of follow-up was 34.5 months. The primary objective of this trial was to examine the effect of ACTOS on mortality and macrovascular morbidity in patients with type 2 diabetes mellitus who were at high risk for macrovascular events. The primary efficacy variable was the time to the first occurrence of any event in the cardiovascular composite endpoint (see *Table 5*). Although there was no statistically significant difference between ACTOS and placebo for the 3-year incidence of a first event within this composite, there was no increase in mortality or in total macrovascular events with ACTOS.

Table 5. Number of First and Total Events for Each Component Within the Cardiovascular Composite Endpoint

	Placebo N=2633		ACTOS N=2605	
	First Events (N)	Total events (N)	First Events (N)	Total events (N)
Cardiovascular Events				
Any event	572	900	514	803
All-cause mortality	122	186	110	177
Non-fatal MI	118	157	105	131
Stroke	96	119	76	92
ACS	63	78	42	65
Cardiac intervention	101	240	101	195
Major leg amputation	15	28	9	28
Leg revascularization	57	92	71	115

Postmarketing reports of new onset or worsening diabetic macular edema with decreased visual acuity have also been received (see **PRECAUTIONS, General, Pioglitazone**).

Glimepiride

Adverse events that occurred in controlled clinical trials with placebo and glimepiride monotherapy, other than hypoglycemia, headache and nausea, also included dizziness (0.3% and 1.7%) and asthenia (1.0% and 1.6%), respectively.

Gastrointestinal Reactions

Vomiting, gastrointestinal pain and diarrhea have been reported with glimepiride, but the incidence in placebo-controlled trials was less than 1%. In rare cases, there may be an elevation of liver enzyme levels. In isolated instances, impairment of liver function (e.g., with cholestasis and jaundice), as well as hepatitis, which may also lead to liver failure, have been reported with sulfonylureas, including glimepiride.

Dermatologic Reactions

Allergic skin reactions (e.g., pruritus, erythema, urticaria and morbilliform or maculopapular eruptions), occur in less than 1% of glimepiride-treated patients. These may be transient and may disappear despite continued use of glimepiride. If those hypersensitivity reactions persist or worsen, the drug should be discontinued. Porphyria cutanea tarda, photosensitivity reactions and allergic vasculitis have been reported with sulfonylureas.

Metabolic Reactions

Hepatic porphyria reactions and disulfiram-like reactions have been reported with sulfonylureas; however, no cases have yet been reported with glimepiride tablets. Cases of hyponatremia have been reported with glimepiride and all other sulfonylureas, most often in patients who are on other medications or have medical conditions known to cause hyponatremia or increase release of antidiuretic hormone. The syndrome of inappropriate antidiuretic hormone (SIADH) secretion has been reported with certain other sulfonylureas, and it has been suggested that these sulfonylureas may augment the peripheral (antidiuretic) action of ADH and/or increase release of ADH.

Hematologic Reactions

Leukopenia, agranulocytosis, thrombocytopenia, hemolytic anemia, aplastic anemia and pancytopenia have been reported with sulfonylureas.

Other Reactions

Changes in accommodation and/or blurred vision may occur with the use of glimepiride. In placebo-controlled trials of glimepiride, the incidence of blurred vision with placebo was 0.7%, and with glimepiride, 0.4%. This is thought to be due to changes in blood glucose and may be more pronounced when treatment is initiated. This condition is also seen in untreated diabetic patients and may actually be reduced by treatment.

Laboratory Abnormalities

Pioglitazone

Hematologic

Pioglitazone may cause decreases in hemoglobin and hematocrit. The fall in hemoglobin and hematocrit with pioglitazone appears to be dose-related. Across all clinical studies, mean hemoglobin values declined by 2% to 4% in patients treated with

pioglitazone. These changes generally occurred within the first four to 12 weeks of therapy and remained relatively stable thereafter. These changes may be related to increased plasma volume associated with pioglitazone therapy and have rarely been associated with any significant hematologic clinical effects (see **PRECAUTIONS, General, Pioglitazone, Hematologic**).

Serum Transaminase Levels

During all clinical studies in the U.S., 14 of 4780 (0.30%) patients treated with pioglitazone had ALT values ≥ 3 times the upper limit of normal during treatment. All patients with follow-up values had reversible elevations in ALT. In the population of patients treated with pioglitazone, mean values for bilirubin, AST, ALT, alkaline phosphatase and GGT were decreased at the final visit compared with baseline. Fewer than 0.9% of patients treated with pioglitazone were withdrawn from clinical trials in the U.S. due to abnormal liver function tests.

In pre-approval clinical trials, there were no cases of idiosyncratic drug reactions leading to hepatic failure (see **PRECAUTIONS, General, Pioglitazone, Hepatic Effects**).

CPK Levels

During required laboratory testing in clinical trials with pioglitazone, sporadic, transient elevations in creatine phosphokinase (CPK) levels were observed. An isolated elevation to greater than 10 times the upper limit of normal was noted in nine patients (values of 2150 to 11400 IU/L). Six of these patients continued to receive pioglitazone, two patients had completed receiving study medication at the time of the elevated value and one patient discontinued study medication due to the elevation. These elevations resolved without any apparent clinical sequelae. The relationship of these events to pioglitazone therapy is unknown.

OVERDOSAGE

Pioglitazone

During controlled clinical trials, one case of overdose with pioglitazone was reported. A male patient took 120 mg/day for four days, then 180 mg/day for seven days. The patient denied any clinical symptoms during this period.

In the event of overdose, appropriate supportive treatment should be initiated according to patient's clinical signs and symptoms.

Glimepiride

Overdosage of sulfonylureas, including glimepiride, can produce hypoglycemia. Mild hypoglycemic symptoms without loss of consciousness or neurologic findings should be treated aggressively with oral glucose and adjustments in drug dosage and/or meal patterns. Close monitoring should continue until the physician is assured that the patient is out of danger. Severe hypoglycemic reactions with coma, seizure, or other neurological impairment occur infrequently, but constitute medical emergencies requiring immediate hospitalization. If hypoglycemic coma is diagnosed or suspected, the patient should be given a rapid intravenous injection of concentrated (50%) glucose solution. This should be followed by a continuous infusion of a more dilute (10%) glucose solution at a rate that will maintain the blood glucose at a level above 100 mg/dL. Patients should be closely monitored for a minimum of 24 to 48 hours, because hypoglycemia may recur after apparent clinical recovery.

DOSAGE AND ADMINISTRATION

General

The use of antihyperglycemic therapy in the management of type 2 diabetes should be individualized on the basis of effectiveness and tolerability. Failure to follow an appropriate dosage regimen may precipitate hypoglycemia.

Dosage Recommendations

Selecting the starting dose of DUETACT should be based on the patient's current regimen of pioglitazone and/or sulfonylurea. Those patients who may be more sensitive to antihyperglycemic drugs should be monitored carefully during dose adjustment. After initiation of DUETACT, patients should be carefully monitored for adverse events related to fluid retention (see **BOXED WARNING** and **WARNINGS, Pioglitazone**). It is recommended that a single dose of DUETACT be administered once daily with the first main meal.

Starting Dose for Patients Currently on Glimepiride Monotherapy

Based on the usual starting dose of pioglitazone (15 mg or 30 mg daily), DUETACT may be initiated at 30 mg/2 mg or 30 mg/4 mg tablet strengths once daily and adjusted after assessing adequacy of therapeutic response.

For patients with type 2 diabetes and systolic dysfunction, see **DOSAGE AND ADMINISTRATION, Special Patient Populations**.

Starting Dose for Patients Currently on Pioglitazone Monotherapy

Based on the usual starting doses of glimepiride (1 mg or 2 mg once daily), and pioglitazone 15 mg or 30 mg, DUETACT may be initiated at 30 mg/2 mg once daily, and adjusted after assessing adequacy of therapeutic response.

For patients who are not currently on glimepiride and may be more sensitive to hypoglycemia, see **DOSAGE AND ADMINISTRATION, Special Patient Populations**.

Starting Dose for Patients Switching from Combination Therapy of Pioglitazone plus Glimepiride as Separate Tablets

DUETACT may be initiated with 30 mg/2 mg or 30 mg/4 mg tablet strengths based on the dose of pioglitazone and glimepiride already being taken. Patients who are not controlled with 15 mg of pioglitazone in combination with glimepiride should be carefully monitored when switched to DUETACT.

Starting Dose for Patients Currently on a Different Sulfonylurea Monotherapy or Switching from Combination Therapy of Pioglitazone Plus a Different Sulfonylurea (e.g., Glyburide, Glipizide, Chlorpropamide, Tolbutamide, Acetohexamide)

No exact dosage relationship exists between glimepiride and the other sulfonylurea agents. Therefore, based on the maximum starting dose of 2 mg glimepiride, DUETACT should be limited initially to a starting dose of 30 mg/2 mg once daily and adjusted after assessing adequacy of therapeutic response.

Any change in diabetic therapy should be undertaken with care and appropriate monitoring as changes in glycemic control can occur. Patients should be observed carefully for hypoglycemia (one to two weeks) when being transferred to DUETACT, especially from longer half-life sulfonylureas (e.g., chlorpropamide) due to potential overlapping of drug effect.

Sufficient time should be given to assess adequacy of therapeutic response. Ideally, the response to therapy should be evaluated using A1C, which is a better indicator of long-term glycemic control than FPG alone. A1C reflects glycemia over the past two to three months. In clinical use, it is recommended that patients be treated with DUETACT for a period of time adequate to evaluate change in A1C (eight to 12 weeks) unless glycemic control as measured by FPG deteriorates.

Special Patient Populations

DUETACT is not recommended for use in pregnancy, nursing mothers or for use in pediatric patients.

In elderly, debilitated or malnourished patients, or in patients with renal or hepatic insufficiency, the initial dosing, dose increments and maintenance dosage of DUETACT should be conservative to avoid hypoglycemic reactions. These patients should be started at 1 mg of glimepiride prior to prescribing DUETACT. During initiation of DUETACT therapy and any subsequent dose adjustment, patients should be observed carefully for hypoglycemia (see **PRECAUTIONS, General, Glimepiride, Hypoglycemia**).

Therapy with DUETACT should not be initiated if the patient exhibits clinical evidence of active liver disease or increased serum transaminase levels (ALT greater than 2.5 times the upper limit of normal) at start of therapy (see **PRECAUTIONS, General, Pioglitazone, Hepatic Effects** and **CLINICAL PHARMACOLOGY, Special Populations, Hepatic Insufficiency, Pioglitazone**). Liver enzyme monitoring is recommended in all patients prior to initiation of therapy with DUETACT and periodically thereafter (see **PRECAUTIONS, General, Pioglitazone, Hepatic Effects** and **PRECAUTIONS, Laboratory Tests**).

The lowest approved dose of DUETACT therapy should be prescribed to patients with type 2 diabetes and systolic dysfunction only after titration from 15 mg to 30 mg of pioglitazone has been safely tolerated. If subsequent dose adjustment is necessary, patients should be carefully monitored for weight gain, edema, or signs and symptoms of CHF exacerbation (see **WARNINGS, Pioglitazone, Cardiac Failure and Other Cardiac Effects**).

Maximum Recommended Dose

DUETACT tablets are available as a 30 mg pioglitazone plus 2 mg glimepiride or a 30 mg pioglitazone plus 4 mg glimepiride formulation for oral administration. The maximum recommended daily dose for pioglitazone is 45 mg and the maximum recommended daily dose for glimepiride is 8 mg.

DUETACT should therefore not be given more than once daily at any of the tablet strengths.

HOW SUPPLIED

DUETACT is available in 30 mg pioglitazone plus 2 mg glimepiride or 30 mg pioglitazone plus 4 mg glimepiride tablets as follows:

30 mg/2 mg tablet: white to off-white, round, convex, uncoated tablet, debossed with 30/2 on one side and 4833G on the other, available in:

NDC 64764-302-30 Bottles of 30

NDC 64764-302-90 Bottles of 90

30 mg/4 mg tablet: white to off-white, round, convex, uncoated tablet, debossed with 30/4 on one side and 4833G on the other, available in:

NDC 64764-304-30 Bottles of 30

NDC 64764-304-90 Bottles of 90

STORAGE

Store at 25°C (77°F); excursions permitted to 15° to 30°C (59° to 86°F) [see USP Controlled Room Temperature]. Keep container tightly closed and protect from moisture and humidity.

HUMAN OPHTHALMOLOGY DATA

Glimepiride

Ophthalmic examinations were carried out in over 500 subjects during long-term studies using the methodology of Taylor and West and Laties et al. No significant differences were seen between glimepiride and glyburide in the number of subjects with clinically important changes in visual acuity, intraocular tension or in any of the five lens-related variables examined.

Ophthalmic examinations were carried out during long-term studies using the method of Chylack et al. No significant or clinically meaningful differences were seen between glimepiride and glipizide with respect to cataract progression by subjective LOCS II grading and objective image analysis systems, visual acuity, intraocular pressure and general ophthalmic examination.

MEDICATION GUIDE
DUETACT (doo-et' -äct)
(pioglitazone and glimepiride) tablets

Read this Medication Guide carefully before you start taking DUETACT and each time you get a refill. There may be new information. This information does not take the place of talking with your doctor about your medical condition or your treatment. If you have any questions about DUETACT, ask your doctor or pharmacist.

What is the most important information I should know about DUETACT?

DUETACT can cause serious side effects, including **new or worse heart failure**.

- Pioglitazone, one of the medicines in DUETACT, can cause your body to keep extra fluid (fluid retention), which leads to swelling (edema) and weight gain. Extra body fluid can make some heart problems worse or lead to heart failure. Heart failure means your heart does not pump blood well enough.
- If you have severe heart failure, you cannot start DUETACT.
- If you have heart failure with symptoms (such as shortness of breath or swelling), even if these symptoms are not severe, DUETACT may not be right for you.

Call your doctor right away if you have any of the following:

- swelling or fluid retention, especially in the ankles or legs.
- shortness of breath or trouble breathing, especially when you lie down.
- an unusually fast increase in weight.
- unusual tiredness.

DUETACT can have other serious side effects. See “What are the possible side effects of DUETACT?”

What is DUETACT?

DUETACT is a prescription medicine used with diet and exercise to improve blood sugar (glucose) control in adults with type 2 diabetes.

DUETACT contains two prescription diabetes medicines called pioglitazone (ACTOS) and glimepiride, a sulfonylurea.

Your doctor will decide if you should take DUETACT.

It is important to eat the right foods, lose weight if needed and exercise regularly in order to manage your type 2 diabetes. Diet, weight loss, and exercise are the main treatments for type 2 diabetes and they also help your diabetes medicines work better for you.

DUETACT has not been studied in children and is not recommended for children under the age of 18. The risks of giving DUETACT to a child are not known. See “What are some other possible side effects of DUETACT?”

Who should not take DUETACT?

Do not take DUETACT if you:

- are allergic to any of the ingredients in DUETACT. See the end of this Medication Guide for a complete list of ingredients in DUETACT.
- have a condition called diabetic ketoacidosis. Diabetic ketoacidosis should be treated with insulin.

People with severe heart failure should not start taking DUETACT. See “What is the most important information I should know about DUETACT?”

What should I tell my doctor before taking DUETACT?

Before starting DUETACT, ask your doctor about what the choices are for diabetes medicines and what the expected benefits and possible risks are for you in particular.

Tell your doctor about all of your medical conditions, especially if you:

- **have heart failure.**
- **have kidney problems.**
- **have type 1 (“juvenile”) diabetes or had diabetic ketoacidosis.** These conditions should be treated with insulin.
- **have a type of diabetic eye disease called macular edema** (swelling of the back of the eye).
- **have liver problems.** Your doctor should do blood tests to check your liver before you start taking DUETACT and during treatment as needed.
- **are pregnant or planning to become pregnant.** DUETACT should not be used during pregnancy. It is not known if DUETACT can harm your unborn baby. Talk to your doctor about the best way to control your blood glucose levels while pregnant.
- **are a premenopausal woman (before the “change of life”), who does not have periods regularly or at all.** DUETACT may increase your chance of becoming pregnant. Talk to your doctor about birth control choices while taking DUETACT. Tell your doctor right away if you become pregnant while taking DUETACT.
- **are breastfeeding or plan to breastfeed.** It is not known if DUETACT passes into your milk and if it can harm your baby. You should not take DUETACT if you breastfeed your baby. Talk to your doctor about the best way to control your blood glucose levels while breastfeeding.
- **have G6PD deficiency** (an inherited condition where you don’t produce enough of the enzyme (G6PD). Taking glimepiride, one of the medicines in DUETACT, with this condition may cause your red blood cells to be destroyed too quickly (hemolytic anemia).

Tell your doctor about all the medicines you take including prescription and nonprescription medicines, vitamins and herbal supplements. DUETACT and some of your other medicines can affect each other. You may need to have your dose of DUETACT or certain other medicines adjusted. Certain other medicines can affect your blood sugar (glucose) control.

Know the medicines you take. Keep a list of your medicines and show it to your doctor and pharmacist before you start a new medicine. They will tell you if it is okay to take DUETACT with other medicines.

How should I take DUETACT?

- Take DUETACT exactly as prescribed.
- Your doctor may need to change your dose of DUETACT to control your blood glucose. Do not change your dose unless told to do so by your doctor.
- DUETACT may be prescribed alone or with other diabetes medicines. This will depend on how well your blood sugar is controlled.
- Take DUETACT one time each day with the first meal.
- If you miss a dose of DUETACT, take your next dose as prescribed unless your doctor tells you differently. Do not take two doses at one time the next day.
- If you take too much DUETACT, call your doctor or poison control center right away.
- If your body is under stress, for example: due to fever, infection, trauma (such as a car accident), or surgery, the dose of your diabetes medicines may need to be changed. Call your doctor right away.

- Stay on your diet and exercise programs and test your blood sugar regularly while taking DUETACT.
- Your doctor should do blood tests before starting DUETACT and from time to time to check your liver, kidneys and blood cells.
- Your doctor should also do regular blood tests (for example, hemoglobin A1C) to check how well your blood sugar is controlled with DUETACT.
- Your doctor should check your eyes regularly. Some people have had vision changes due to swelling in the back of the eye, called macular edema, while taking DUETACT.
- It may take two to three months to see the full effect on your blood sugar level.

What are other possible side effects of DUETACT?

DUETACT can cause other serious side effects, including:

- **The chance of death from serious heart or blood vessel problems may be higher** when using a sulfonylurea, an ingredient in DUETACT. The risk may be higher when compared to using diet alone or diet and insulin to control blood sugar levels.
- **Low blood sugar (hypoglycemia).** Lightheadedness, dizziness, shakiness or hunger may indicate that your blood sugar is too low. This can happen if you skip meals, if you use another medicine that lowers blood sugar or if you have certain medical problems. Call your doctor if low blood sugar levels are a problem for you.
- **Weight gain.** Pioglitazone, one of the medicines in DUETACT, can cause weight gain that may be due to fluid retention or extra body fat. Weight gain due to fluid retention can be a serious problem for people with certain heart problems. See “What is the most important information I should know about DUETACT?”
- **Liver problems.** It is important for your liver to be working normally when you take DUETACT. Your doctor should do blood tests to check your liver before you start taking DUETACT and during treatment as needed. Call your doctor right away if you have unexplained symptoms such as:
 - nausea or vomiting
 - stomach pain
 - unusual or unexplained tiredness
 - loss of appetite
 - dark urine
 - yellowing of your skin or the whites of your eyes
- **Macular edema** (diabetic eye disease with swelling in the back of the eye). Tell your doctor right away if you have any changes in your vision. Your doctor should check your eyes regularly.
- **Fractures (broken bones),** usually in the hand, upper arm or foot in women. Talk to your doctor for advice on how to keep your bones healthy. It is not known if DUETACT can affect the bones of children.
- **Bladder cancer.** There may be an increased chance of having bladder cancer when you take DUETACT. You should not take DUETACT if you are receiving treatment for bladder cancer. Tell your doctor right away if you have any of the following symptoms of bladder cancer:
 - blood or a red color in your urine
 - an increased need to urinate
 - pain while you urinate

- **Low red blood cell count (anemia).**
- **Ovulation** (release of an egg from an ovary in a woman) leading to pregnancy. Ovulation may happen when premenopausal women who do not have regular monthly periods take DUETACT. This can increase the chance of pregnancy. See “What should I tell my doctor before taking DUETACT?”

Other common side effects of DUETACT are:

- coldlike symptoms (upper respiratory infection)
- headache
- urinary tract infection
- diarrhea
- nausea
- arm or leg pain

Tell your doctor if you have any side effect that bothers you or that does not go away. These are not all the side effects of DUETACT. For more information, ask your doctor or pharmacist.

Call your doctor for medical advice about side effects. You may report side effects to FDA at 1-800-FDA-1088.

How should I store DUETACT?

- Store DUETACT at 59°F to 86°F (15°C to 30°C). Keep DUETACT in the original container to protect from light.
- Keep the DUETACT bottle tightly closed and protect from getting wet (away from moisture and humidity).

Keep DUETACT and all medicines out of the reach of children.

General information about DUETACT

Medicines are sometimes prescribed for purposes other than those listed in a Medication Guide. Do not use DUETACT for a condition for which it is not prescribed. Do not give DUETACT to other people, even if they have the same symptoms you have. It may harm them.

This Medication Guide summarizes the most important information about DUETACT. If you would like more information, talk with your doctor. You can ask your doctor or pharmacist for information about DUETACT that is written for healthcare professionals. For more information, go to www.duetact.com or call 1-877-825-3327.

What are the ingredients in DUETACT?

Active Ingredients: pioglitazone and glimepiride

Inactive Ingredients: croscarmellose sodium, lactose monohydrate, magnesium stearate, hydroxypropyl cellulose, polysorbate 80 and microcrystalline cellulose

Always check to make sure that the medicine you are taking is the correct one. DUETACT tablets look like this:

- 30-mg/2-mg strength tablets—white to off-white, round tablet with “30/2” on one side and “4833G” on the other.
- 30-mg/4-mg strength tablets—white to off-white, round tablet with “30/4” on one side and “4833G” on the other.

This Medication Guide has been approved by the U.S. Food and Drug Administration.
